TAYLOR SPECTRUM

BILICH BORIS

1. INTRODUCTION

2. PRELIMINARIES

2.1. **Notation.** In the article all algebras, including Lie algebras, are complex. For Lie algebra $\mathfrak{g}$ we will use the notation $U\mathfrak{g}$ to denote its enveloping algebra. We will denote by $\mathfrak{g}$-**mod** and **mod**-$\mathfrak{g}$ the categories of left and right $\mathfrak{g}$-modules respectively. We write $\hat{\mathfrak{g}}$ for the set of set of isomorphism classes of simple finite-dimensional $\mathfrak{g}$-modules and $\mathbb{C}$ for trivial bimodule. For $\mathfrak{g}$-module V can be defined vector spaces

$$(1) \qquad V^{\mathfrak{g}} = \{v \in V : g \cdot v = 0 \; \forall g \in \mathfrak{g}\},$$

called invariants and

$$(2) \qquad V_{\mathfrak{g}} = V/gV,$$

called coinvariants. It is known , that $\square^{\mathfrak{g}}$ and $\square_{\mathfrak{g}}$ are actually functors from $\mathfrak{g}$-**mod** (or **mod**-$\mathfrak{g}$) to the category of vector spaces over $\mathbb{C}$, isomorphic to $\mathrm{Hom}_{\mathfrak{g}}(\mathbb{C}, V)$ and $\mathbb{C} \otimes_{U\mathfrak{g}} V$ respectively.

2.2. **Functors between categories of modules.** For the rest of this section we will denote by $\mathfrak{g}$ an arbitary finite-dimensional Lie algebra. We define two functors $\square^*$:
$\mathfrak{g}$-**mod**$^{op} \to$ **mod**-$\mathfrak{g}$ and $\square^{\circ}$: $\mathfrak{g}$-**mod** $\to$ **mod**-$\mathfrak{g}$ as follows. The first $\square^*$, called duality functor, sends $\mathfrak{g}$-module V to it's dual vector space, on which the right action of $\mathfrak{g}$ is defined as

$$(f \cdot g)(v) = f(g \cdot v), \quad \text{for all } f \in V^*, \; v \in V, \; g \in \mathfrak{g}.$$

The second $\square^{\circ}$, called antipode functor, sends V to itself as a vector space with right action

$$v \cdot g = -g \cdot v, \quad \text{for all } v \in V, \; g \in \mathfrak{g}.$$

These two functors define equivalence of categories $\mathfrak{g}$-**mod**, **mod**-$\mathfrak{g}$, $\mathfrak{g}$-**mod**^{op} and **mod**-$\mathfrak{g}$^{op}. We will also denote by $\square^*$ and $\square^{\circ}$ functors from category of right $\mathfrak{g}$-modules to left $\mathfrak{g}$-modules, defined the same way. It is easy to see, that $(\square^*)^*$ and $(\square^{\circ})^{\circ}$ are naturally isomorphic to the identity functor.

Another pair of very important functors are $\square \otimes_{\mathbb{C}} \square$: **mod**-$\mathfrak{g} \times \mathfrak{g}$-**mod** $\to \mathfrak{g}$-**mod** and $\mathrm{Hom}_{\mathbb{C}}(\square, \square)$: $\mathfrak{g}$-**mod**$^{op} \times \mathfrak{g}$-**mod** $\to \mathfrak{g}$-**mod**. If $V \in$ **mod**-$\mathfrak{g}$ and $W \in \mathfrak{g}$-**mod**, then $V \otimes_{\mathbb{C}} W$ is the tensor product of V and W as vector space with action of $\mathfrak{g}$, fully determined by the formula

$$g \cdot v \otimes w = v \otimes (g \cdot w) - (v \cdot g) \otimes w, \text{ for all } w \in W, \; v \in V, \; g \in \mathfrak{g}$$

. The Hom functor is defined as

$$\mathrm{Hom}_{\mathbb{C}}(V, W) = V^* \otimes_{\mathbb{C}} W.$$

For $V, W \in \mathfrak{g}\text{-}\mathbf{mod}$ (resp. $\mathbf{mod}\text{-}\mathfrak{g}$), we will denote by $V \otimes W$ left $\mathfrak{g}$-module $V^\circ \otimes_\mathbb{C} W$ (resp. $V \otimes_\mathbb{C} W^\circ$).

For $V \in \mathfrak{g}\text{-}\mathbf{mod}$ and $S \in \hat{\mathfrak{g}}$, we will write V_S for the $\mathfrak{g}$-module $S \otimes_\mathbb{C} V$. If S is one-dimensional, it is fully determined by the character $\lambda \in (\mathfrak{g}/[\mathfrak{g}, \mathfrak{g}])$ and in this case we will simply write V_λ for it. For example, $\mathbb{C}_\lambda$ stands for one-dimensional module with action, given by $g \cdot s = \lambda(g)s$ for all $s \in \mathbb{C}_\lambda$ and $g \in \mathfrak{g}$. We will also use the notation V_{-S} for the module $S^* \otimes_\mathbb{C}$, which is motivated by the fact, that if S is again one-dimensional with character λ, then V_{-S} is isomorphic to $V_{-\lambda}$.

2.3. **Homology and cohomology of Lie algebras.** In this paragraph we recall the definitions of Lie algebra cohomology, which can be found in any related textbook .

Definition 1. *For $V \in \mathfrak{g}\text{-}\mathbf{mod}$ and for all $k \in \mathbb{Z}_{\geq 0}$ the homology functors are defined as*

$$(3) \qquad H_k(\mathfrak{g}, V) = \operatorname{Tor}_k^{U\mathfrak{g}}(\mathbb{C}, V),$$

and, dually, the cohomology as

$$(4) \qquad H^k(\mathfrak{g}, V) = \operatorname{Ext}_{U\mathfrak{g}}^k(\mathbb{C}, V).$$

The homology can be computed using Chevalley-Eilenberg free resolution of the trivial $\mathfrak{g}$ module $\mathbb{C}$. It has $F_k = U\mathfrak{g} \otimes_\mathbb{C} \bigwedge^k \mathfrak{g}$ in degree k with the differential given by

$$d(u \otimes g_1 \wedge \cdots \wedge g_p) = \sum_{i=1}^p (-1)^{i+1} u g_i \otimes g_1 \wedge \cdots \wedge \hat{g}_i \wedge \cdots \wedge g_p +$$

$$(5) \qquad + \sum_{i<j} (-1)^{i+j} u \otimes [g_i, g_j] \wedge \cdots \wedge \hat{g}_i \cdots \wedge \hat{g}_j \cdots \wedge g_p, \text{ where } u \in U\mathfrak{g}, \ g_i \in \mathfrak{g}.$$

The following fact about homology will be used in the text.

Lemma 1. *Let $V \in \mathbf{mod}\text{-}\mathfrak{g}$ and $W \in \mathfrak{g}\text{-}\mathbf{mod}$. Then*

$$\operatorname{Tor}_k^{U\mathfrak{g}}(V, W) \cong \operatorname{Tor}_k^{U\mathfrak{g}}(\mathbb{C}, V \otimes_\mathbb{C} W) = H_k(\mathfrak{g}, V \otimes_\mathbb{C} W),$$

for all $k \in \mathbb{Z}_{\geq 0}$.

Proof. Since functors $\mathbb{C} \otimes_{U\mathfrak{g}} (\square \otimes_\mathbb{C} W)$ and $\square \otimes_{U\mathfrak{g}} W$ are naturally isomorphic, it suffices to show, that if $P_\bullet \to V$ is a flat resolution of V, then $P_\bullet \otimes_\mathbb{C} W$ is a flat resolution of $V \otimes_\mathbb{C} W$.

By definition, flatness of P_k means exactness of functor $P_k \otimes_{U\mathfrak{g}} \square$. Using properties of tensor product we obtain an isomorphism of functors $(P_k \otimes_\mathbb{C} W) \otimes_{U\mathfrak{g}} \square$ and $P_k \otimes_{U\mathfrak{g}} (W \otimes_\mathbb{C} \square)$. The last fucntor is the composition of exact functors, so it is also exact, hence $P_k \otimes_\mathbb{C} W$ is flat. ∎

A useful variation of Poincare duality holds for finite dimensional Lie algebras. Let $n = \dim \mathfrak{g}$. We endow one-dimensional vector space $\bigwedge^n \mathfrak{g}$ with structure of left $\mathfrak{g}$-module, which extends adjoint action by Leibnitz rule.

Theorem 2 (Poincare duality). *For $0 \leq k \leq n$ and any left $\mathfrak{g}$-module V, there are vector space isomorphism*

$$H^k(\mathfrak{g}, V^*) \cong H_k(\mathfrak{g}, V)^*,$$

ref weibel

ref weibel, guichardet

and

$$H^k(\mathfrak{g}, V) \cong H_{n-k}(\mathfrak{g}, (\bigwedge^n \mathfrak{g})^* \otimes_{\mathbb{C}} V),$$

natural in V. Consequently

$$H^k(\mathfrak{g}, V^*) \cong H^{n-k}(\mathfrak{g}, \bigwedge^n \mathfrak{g} \otimes_{\mathbb{C}} V)^*.$$

3. Taylor spectrum of $\mathfrak{g}$-module

Let $\mathfrak{g}$ be an arbitary Lie algebra and V be a left $\mathfrak{g}$-module. Recall, that $\hat{\mathfrak{g}}$ is the set of isomorphism classes of simple finite dimensional $\mathfrak{g}$-modules.

Definition 2. *The Taylor spectrum of V is the subset of $\hat{\mathfrak{g}}$, defined as*

$$\sigma_{\mathfrak{g}}(V) = \{S \in \hat{\mathfrak{g}} \mid \exists k \colon \mathrm{Tor}_k^{U\mathfrak{g}}(S^*, V) \neq 0\}.$$

We will simply write $\sigma(V)$ instead of $\sigma_{\mathfrak{g}}(V)$ if it is clear what Lie algebra is considered.

Let us provide several equivalent definitions, in order to use later.

Theorem 3. *For an arbitary $S \in \mathfrak{g}$, the following are equivalent:*

(1) $S \in \sigma(V)$;
(2) $H_k(\mathfrak{g}, V_{-S}) \neq 0$ *for some k;*
(3) $H^k(\mathfrak{g}, \bigwedge^n \mathfrak{g} \otimes_{\mathbb{C}} V_{-S}) \neq 0$ *for some k;*
(4) $S^* \otimes_{\mathbb{C}} \bigwedge^n \mathfrak{g} \in \sigma(V^*)$

Proof. $1 \Rightarrow 2$ This follows immediatly from Lemma 1.
$2 \Rightarrow 3$ Poincare duality (Theorem 2).
$3 \Rightarrow 4$ $\underline{\hspace{5cm}}$ finish proof
